

Test Strategy

Testing Approach

Testing was performed using a combination of manual functional testing through the application UI and API-level testing via Postman. The approach focused on black-box, scenario-driven testing covering positive (happy path) flows, negative/invalid-input flows, boundary value analysis (Ex, loan thresholds, account balances), and targeted security checks (authorization and data exposure). Both UI and backend responses (status codes and payloads) were validated to catch issues that aren't visible from the UI alone, such as incorrect HTTP status codes or exposed sensitive data.

Areas Prioritized and Why

- Financial transactions (Transfer Funds, Bill Pay, Request Loan) highest priority, as defects here directly risk incorrect money movement, negative balances, or unauthorized fund access.
- Authentication and authorization (Login, Registration, account ownership checks) — prioritized due to the security impact of allowing unauthorized access to other users' accounts, transactions, or data.
- Data integrity on profile/contact updates — prioritized because silent update failures and misleading confirmation messages can erode user trust and mask real account state.
- Input validation across forms and API requests — prioritized since several critical flows (loans, transfers) accepted invalid or empty values instead of rejecting them.

Assumptions Made

- The test environment's behavior is representative of production behavior.
- Test accounts and user data used during execution were valid and adequately represented real usage scenarios.
- Only functional and security behavior was in scope; non-functional requirements (performance, load, accessibility) were not part of the defined testing objectives.

Areas Intentionally Left Untested

- Performance and load testing (concurrent users, response times under load).
- Cross-browser and cross-device UI/responsiveness testing.
- Full regression of the Admin panel beyond the Loan Processor configuration used to support loan-related test cases.
